Review: Partial Fractions

Given an expression $\frac{f(x)}{g(x)}$, we can alternatively express it as a series of fractions [assuming the degree of $f(x)$ is smaller than the degree of $g(x)$]:

Case 1: $g(x)$ can be expressed as a product of distinct linear factors $(x-\lambda)$ (i.e. $g(x) = (x-\lambda_1) \dots (x-\lambda_n)$)

$$\rightarrow \frac{f(x)}{g(x)} = \frac{A}{x-\lambda_1} + \frac{B}{x-\lambda_2} + \dots + \frac{N}{x-\lambda_n} \quad [\text{for some } A, B, \dots, N \in \mathbb{R}]$$

\hookrightarrow Can be alternatively expressed as $f(x) = A(x-\lambda_2) \dots (x-\lambda_n) + B(x-\lambda_1)(x-\lambda_3) \dots$

Case 2: $g(x)$ can be expressed as a product of distinct linear factors $(x-\lambda)^n$

$$\rightarrow \frac{f(x)}{g(x)} = \frac{A}{(x-\lambda_1)^1} + \frac{B}{(x-\lambda_1)^2} + \dots + \frac{N}{(x-\lambda_1)^{n_1}} + \frac{M}{(x-\lambda_2)^1} + \dots + \frac{Z}{(x-\lambda_n)^{n_n}} \quad (\text{e.g.})$$

Case 3: $g(x)$ contains irreducible quadratic factors [polynomials of degree ≥ 2]

$$\rightarrow \frac{f(x)}{g(x)} = \frac{Ax+B}{h(x)} + \frac{C}{(x-\lambda)} \quad (\text{e.g.}) \quad [\text{Repeated quadratics: same method as Case 2}]$$

Review: Linear Algebra

Intro to Differential Equations

4/10/23
Lecture 4
(cont.)

Def: Implicit Differential Equations (§3.1)

An implicit differential equation [of order r] is an equation that can be written in the form:

$$F(t, y, y', y'', \dots, y^{(r)}) = 0 \quad [\text{Implicit differential eq. of order } r]$$

Definitions

- The order r of an equation is the order of the highest derivative $y^{(r)}$ in the equation
- A solution to an implicit differential equation of order r is a function $y: I \rightarrow \mathbb{R}$, differentiable at least r times, such that:

$$F(t, y(t), y'(t), \dots, y^{(r)}(t)) = 0 \quad \forall t \in I$$

(*) A solution may also be referred to as an integral curve / soln. curve.

(*) I being expressed as an interval subset of \mathbb{R}

(*) Examples

1) A zeroth order equation is any equation containing no derivatives of y

↳ Includes polynomials of y , e.g. $y^2 + y = 2$ [0th order]

2) A first order equation is any equation $f(y, t) + g(y', t) + h(t) = 0$

↳ (*) Logistic equation: $y' - y(b - cy) = 0 \rightarrow y(t) = C_1 \exp 2t + C_2 \exp t$

↳ (*) $\exp f(t) = e^{f(t)}$

Normal Form (§3.2)

A differential equation of order r is said to be in normal form [or an explicit differential equation [of order r]] if it is in the form:

$$y^{(r)} = F(t, y, y', y'', \dots, y^{(r-1)}) \quad [\text{Normal form}]$$

↳ A solution y is thus a function (differentiable at least r times) satisfying the equation.

↳ An implicit differential equation can be put in normal form if its highest derivative is expressible in terms of its lower derivatives

First-Order Differential Equations

4/12/23
Lecture 5

First-Order Differential Equations

Given an explicit first-order differential equation $y' = F(t, y)$, a solution is a differentiable function $y: I \rightarrow \mathbb{R}$ s.t. $y'(t) = F(t, y(t)) \forall t \in I$.

Definitions

• A general solution for an explicit first-order differential equation is the family of functions $y(t; C)$, dependent on a constant $C \in \mathbb{R}$, s.t.:

1) $y(t; C_0)$ satisfies the equation for all valid parameters C_0 .

2) Every solution is of the form $y(t; C_1)$ for some valid parameter C_1 .

→ • A particular solution is a function $y(t; C_0)$ for some fixed value C_0 .

Initial Value Problems

Def: An initial value problem is a pair of two conditions any solution must satisfy:

1) A differential equation $y' = F(t, y)$

2) A specific point $y(t_0) = y_0$ [The initial condition]

(*) Direction Fields

A direction field is a plot where at each point (t_0, y_0) , there is plotted a line segment with slope $y' = F(t_0, y_0)$.

Ex: $y' = y(3-y) \rightarrow$  (e.g.)

Def: 1st-Order Linear Differential Equation (§3.3)

A first-order linear differential equation is a differential equation that can be written in the form:

$$y' + f(t)y = g(t) \quad [\text{First-Order Linear Differential Equation}]$$

↳ $f(t)$ and $g(t)$ are referred to as coefficient functions

Solutions of First-Order Linear Differential Equations

4/14/23
Lecture 6

Solving First-Order Linear Differential Equations

A first-order linear differential equation $y' + f(t)y = g(t)$ can be solved as follows:

$$y' + f(t)y = g(t) \rightarrow \text{Define integrating factor } \mu(t) = \int f(t) dt$$

$$\rightarrow \mu(t)y' + \mu(t)f(t)y = \frac{d}{dt}(\mu(t)y) [= g(t)]$$

$$\rightarrow y = \frac{1}{\mu(t)} \left(\int g(t) dt \right) = \frac{1}{\mu(t)} \int g(t) dt + \frac{C}{\mu(t)} \quad [\text{General solution}]$$

\hookrightarrow Given an initial condition $y(t_0) = y_0$, we can find a particular solution $y(t; t_0)$.

(*) Intervals of Existence

Given a 1st-order differential equation with coefficient functions $f: D \rightarrow \mathbb{R}$ and $g: E \rightarrow \mathbb{R}$ for some intervals D, E , and initial condition $y(t_0) = y_0$, the interval of existence of the particular solution satisfying the initial condition is the largest interval I such that:

1) $t_0 \in I$

2) $I \subseteq D$; and $I \subseteq E$

(*) The interval of existence will always be a subset of the domains of the coefficient functions f and g .

(*) Lemma: Given a linear differential equation $y' + f(t)y = g(t)$ satisfied by two differentiable functions $y_0, y_1: I \rightarrow \mathbb{R}$ [possibly distinct]:

$$\rightarrow 1) \exists \text{ a constant } C \text{ s.t. } y_0(t) = y_1(t) + \frac{C}{\mu(t)} \quad \forall t \in I$$

$$\rightarrow 2) \text{ If } \exists t_0 \in I \text{ s.t. } y_0(t_0) = y_1(t_0), \text{ then } y_0 = y_1$$

(*) Observation: If $\mu(t)$ is an integrating factor, any function $C\mu(t)$ ($C \neq 0$) is also a valid integrating factor.

Differential Forms

4/17/23
ecture 7

Implicit Equations (§3.4)

Def: An implicit equation is an equation that can be written in the form: $F(t, y) = 0$

Def: Given a function $F(t, y)$ and a constant $C \in \mathbb{R}$, we call an equation a level set of F if it is in the form:

$$F(t, y) = C \quad [\text{Level set of } F] \quad (*) \text{ Also considered an implicit equation}$$

Ex: $t^2 + y^2 = r^2$ [circle of radius r]

↳ Explicit variants have discontinuities; this does not

Differential Forms

Motivation: How we can take the derivative of an implicit equation?

Def: Differential Forms

A differential form is an equation of the form:

$$P(t, y)dt + Q(t, y)dy \quad [\text{Differential form}],$$

where dy , dt are placeholders associated with y and t , called differentials.

Differentials of Equations

Given a function $F(t, y)$ the differential of F is:

$$dF = \frac{\partial F}{\partial t}(t, y)dt + \frac{\partial F}{\partial y}(t, y)dy \quad [\text{Differential of } F(t, y)]$$

↳ Can be used to solve for dy/dt , e.g.

Separable Equations

4/19/23
Lecture 8

Obtaining Differential Forms (§3.5)

Given an explicit 1st-order linear differential equation $y' = \frac{dy}{dt} = f(t, y)$, it can be rewritten as a differential form equation as follows:

$$\frac{dy}{dt} = f(t, y) \xrightarrow{\times dt} dy = f(t, y) dt$$

$$\xrightarrow{-f(t, y) dt} -f(t, y) dt + dy = 0$$

$$\xrightarrow{\times p(t, y)} -f(t, y)p(t, y) dt + p(t, y) dy = 0 \quad [\text{for some integrating factor } p]$$

(*) Meant to make a more readily integrable equation

Separable Differential Equations

Def.: A separable differential equation is an equation of the form:

$$\boxed{\frac{dy}{dt} = f(t)g(y)} \quad [\text{Separable differential equation}]$$

Can be rearranged into $-f(t)dt + \frac{dy}{g(y)} = 0 \quad [= dF]$

$$\longrightarrow F(t, y) = \int (-f(t)) dt + \int \left(\frac{1}{g(y)}\right) dy + C$$

Solutions of Separable Equations

Given a separated equation $P(t)dt + Q(y)dy = 0$:

1) Define function $F(t, y) := \int P(t)dt + \int Q(y)dy$

$$\rightarrow \text{s.t. } dF = P(t)dt + Q(y)dy [= 0]$$

2) $dF = 0 \longrightarrow \boxed{F(t, y) = C}$ [General solution], for arbitrary $C \in \mathbb{R}$

$$\rightarrow \text{Alt.: } \int P(t)dt + \int Q(y)dy = C$$

Can find values for C to make a particular solution

Exact Differential Equations

4/21/23
Lecture 9

Exact Differential Equations

Def: An exact differential equation is an equation of the more general form: $y' = f(t, y)$ and can be solved by rearranging the terms and multiplying by an integrating factor $\mu(t)$ into the form:

$$-f(t, y)\mu(t, y)dt + \mu(t, y)dy = \boxed{P(t, y)dt + Q(t, y)dy = 0} \quad [\text{Differential form}]$$

Potential Functions

To find the integrating factor $\mu(t, y)$, we first find a potential function.

Def: A potential function is a function $F(t, y)$ such that:

$$\boxed{dF = P(t, y)dt + Q(t, y)dy} \quad \left\{ \begin{array}{l} \frac{\partial F}{\partial t} = P(t, y) \\ \frac{\partial F}{\partial y} = Q(t, y) \end{array} \right. \quad [\text{Potential function}]$$

Def: Given two-variable functions $P, Q: D \rightarrow \mathbb{R} (D \subseteq \mathbb{R}^2)$, the differential form $Pdt + Qdy$ is considered exact if \exists a continuously differentiable function $F: D \rightarrow \mathbb{R}$ s.t. $dF = Pdt + Qdy$. [\exists a potential function]

↳ Condition: We assume P and Q are continuously differentiable.
→ F must have continuous second-order partial derivatives.

$$\rightarrow \frac{\partial F}{\partial y \partial t} = \frac{\partial F}{\partial t \partial y} \quad [\text{per Clairaut's}] \rightarrow \boxed{\frac{\partial Q}{\partial t} = \frac{\partial P}{\partial y}}$$

→ Closedness

Given $P, Q: D \rightarrow \mathbb{R} (D \subseteq \mathbb{R}^2)$, we say the differential form $Pdt + Qdy$ is closed if:

$$\boxed{\frac{\partial P}{\partial y} - \frac{\partial Q}{\partial t} = 0} \quad [\text{Closedness}]$$

THM

Let $P, Q: I \times J \rightarrow \mathbb{R}$ be continuously differentiable functions across some intervals I, J [s.t. $I \times J$ is a rectangle.] Then:

$$\boxed{"Pdt + Qdy \text{ is closed."} \leftrightarrow "Pdt + Qdy \text{ is exact."}$$

Existence & Uniqueness Theorems

4/24/23

Lecture 10

The Integrating Factor

The role of the integrating factor is to make non-exact equations, exact.

Def: Given continuous functions $P, Q: D \rightarrow \mathbb{R}$ ($D \subseteq \mathbb{R}^2$), we say that a function $\mu: D \rightarrow \mathbb{R}$ is an integrating factor for the differential form equation $P(t, y)dt + Q(t, y)dy = 0$ if: 1) $\mu(t, y) \neq 0$ for every $(t, y) \in D$; and 2) $\mu(t, y)P(t, y)dt + \mu(t, y)Q(t, y)dy$ is exact.

$$\rightarrow 2) \text{ satisfied, iff: } \boxed{\frac{\partial}{\partial t}(\mu(t, y)P(t, y)) = \frac{\partial}{\partial y}(\mu(t, y)Q(t, y)) = 0} \quad [\text{for I.F. } \mu]$$

Existence Theorem (83.6)

Let $f: I \times J \rightarrow \mathbb{R}$ be a continuous two-variable function defined on a rectangle $I \times J$ for intervals I, J . Then, given any point $(t_0, y_0) \in I \times J$, the initial value problem $\{y' = f(t, y); y(t_0) = y_0\}$ has a solution defined on some interval $I' \subseteq I$ [$t_0 \in I'$]. The solution is defined at least until the solution curve $t \mapsto f(t, y(t))$ leaves the rectangle $I \times J$.

Uniqueness Theorem

Let $f: I \times J \rightarrow \mathbb{R}$ be a continuous two-variable function defined on a rectangle $I \times J$ for intervals I, J . Furthermore, suppose $\frac{\partial f}{\partial y}$ exists and is continuous on all of $I \times J$. Let $(t_0, y_0) \in I \times J$, and suppose we have two solutions $y(t), \tilde{y}(t)$ to the same IVP:

- 1) $y'(t) = f(t, y(t))$ and $\tilde{y}'(t) = f(t, \tilde{y}(t))$ for every t , and
- 2) $y(t_0) = y_0$ and $\tilde{y}(t_0) = y_0$.

Then, for every t s.t. $(t, y(t))$ and $(t, \tilde{y}(t))$ remain in $I \times J$, we have: $\boxed{y(t) = \tilde{y}(t)}$

↳ Consequence: Different solution curves cannot cross.

Autonomous Equations

4/26/23
ecture 11

Autonomous Equations (§3.7)

Def: A 1st-order differential equation is called autonomous if it can be written in the form: $y' = f(y)$
(Alt: Equation does not depend on t)

↳ Can be used to study the qualitative properties of solutions, e.g. via direction fields.

Properties of Autonomous Equations

- 1) Since autonomous equations do not depend on t , the direction field of an autonomous equation will not change left-to-right, only up/down.
- 2) Let $y_0(t)$ be a particular solution and $c \in \mathbb{R}$ be a constant. Then $y_0(t+c)$ is also a solution; in fact:

$$(y_0(t+c))' = y_0'(t+c) = f(y_0(t+c))$$

- 3) Suppose $y_0 \in \mathbb{R}$ is such that $f(y_0) = 0$. Then the constant function $y(t) := y_0$ for all t is a solution to $y' = f(y)$. Such a number y_0 is called an equilibrium point and the constant function $y(t) := y_0$ is called an equilibrium solution.

Non-Equilibrium Solutions

Any non-equilibrium solution will be asymptotic to one of the equilibrium solutions. Furthermore, it will be either strictly increasing or strictly decreasing.

Def: Given an autonomous equation with initial condition (t_0, y_0) , it is called strictly increasing if $y' = f(y_0) > 0$. Conversely, it is called strictly decreasing if $y' = f(y_0) < 0$.

$(f(y_0) = 0 \rightarrow \text{equilibrium solution})$ Ex:

The qualitative behavior of solutions to an autonomous equation can notably be visualized using a phase line.

Autonomous Equations (cont.)

4/26/23
Lecture 11
(cont.)

Autonomous Equations (cont.)

Phase Lines

Def: A phase line for an equation $y' = f(y)$ is a plot of the y -axis (displayed horizontally) with the features:

Ex: $+\infty$
 y
 y_0
 y_1
 $-\infty$

equilibrium (stable)
equilibrium (unstable)

1) At every equilibrium point y_0 (where $f(y_0) = 0$), there is a dot.

2) In each region between two equilibrium points, or between an equilibrium point and $\pm\infty$:

i) If $f(y) > 0$ in that region, there is an arrow to the right [y strictly increasing].

ii) Conversely, if $f(y) < 0$, there is an arrow to the left [y strictly decreasing].

3) At each equilibrium point y_0 , if the arrows to its side are pointing toward y_0 , then the dot at y_0 is filled in; otherwise, the dot is not filled in.

Equilibrium Stability

Def: Let $y_0 \in \mathbb{R}$ be an equilibrium point for an autonomous equation $y' = f(y)$. Then, we say that y_0 is:

1) asymptotically stable if, given a solution passing through $(t_0, y_0 + \epsilon)$ for some very small ϵ ($1 \leq \epsilon < 1$, e.g.), that solution will asymptotically approach the solution $y(t) = y_0$.

2) unstable otherwise, i.e. if y_0 is not asymptotically stable.

Analogy: Asymptotically stable equilibrium points "attract" solutions; unstable points repel them.

First-Derivative Test for Stability

Let y_0 be an equilibrium point for autonomous equation $y' = f(y)$, and suppose the function f is differentiable. Then:

1) if $f'(y_0) < 0$, then f is strictly decreasing at y_0 and y_0 is asymptotically stable.

2) if $f'(y_0) > 0$, then f is strictly increasing at y_0 and y_0 is unstable.

3) if $f'(y_0) = 0$, the test is inconclusive.

(*) Stability Application: "Given a slight measurement error, will this still be the equilibrium?"

Second-Order Linear Equations

4/28/23

Lecture 12

Second-Order Linear Equations (§4.1)

Def: A second-order linear differential equation is a differential equation which can be expressed in the form:

$$y''(t) + p(t)y' + q(t)y = g(t) \quad [2^{\text{nd}}\text{-order linear diff. equation}]$$

Notes:

- p, q, g referred to as coefficient functions; $g(t)$ referred to as the forcing term
- A 2^{nd} -order linear eq. is said to be homogeneous if it can be expressed in the form: $y''(t) + p(t)y' + q(t)y = 0$ [if $g(t) = 0$]

(*) Existence and Uniqueness Theorems

THM: Suppose $p, q, g: I \rightarrow \mathbb{R}$ are continuous functions with domain interval $I \subseteq \mathbb{R}$. Then, given $t_0 \in I$ and any two real numbers $y_0, y_1 \in \mathbb{R}$ there is a unique function $y: I \rightarrow \mathbb{R}$ satisfying the IVP: (i) $y'' + p(t)y' + q(t)y = g(t)$; (ii) $y(t_0) = y_0$; $y'(t_0) = y_1$.

Linear Combinations

Given functions $y_1, y_2, \dots, y_n: I \rightarrow \mathbb{R}$, a linear combination of y_1, y_2, \dots, y_n is any function of the form:

$$C_1 y_1 + C_2 y_2 + \dots + C_n y_n: I \rightarrow \mathbb{R} \quad \text{for constants } C_1, C_2, \dots, C_n \in \mathbb{R}$$

Proposition: Linear Combinations

Prop.: Suppose $y_1(t), y_2(t)$ are solutions to the homogeneous second-order differential equation $y'' + p(t)y' + q(t)y = 0$. Then, for any $C_1, C_2 \in \mathbb{R}$, the function $C_1 y_1 + C_2 y_2$ is also a solution.

Second-Order Linear Equations (cont.)

4/28/23
Lecture 12
(cont.)

Second-Order Linear Equations (cont.)

Linear Independence

Def: Suppose $y_1, y_2: I \rightarrow \mathbb{R}$ are functions defined on an interval $I \subseteq \mathbb{R}$. We say that y_1, y_2 are linearly independent if: for every $c_1, c_2 \in \mathbb{R}$, if

$$c_1 y_1(t) + c_2 y_2(t) = 0 \text{ for all } t \in I \rightarrow c_1, c_2 = 0, \text{ [Linear Independence]}$$

i.e. if the only linear combination satisfying $c_1 y_1 + c_2 y_2 = 0$ for all t in the domain is the trivial linear combination $0y_1 + 0y_2 = 0$.

If y_1, y_2 are not linearly independent, i.e. \exists a pair of constants c_1, c_2 not both 0 s.t. $c_1 y_1 + c_2 y_2 = 0 \forall t \in I$, then they are called linearly dependent; meaning that one of y_1, y_2 is a constant multiple of the other.

Wronskian

Def: Suppose $u, v: I \rightarrow \mathbb{R}$ are two differentiable functions defined on an interval $I \subseteq \mathbb{R}$. Then we define the Wronskian of u and v to be the function $W: I \rightarrow \mathbb{R}$ defined by:

[Wronskian]

$$W(t) := \det \begin{bmatrix} u(t) & v(t) \\ u'(t) & v'(t) \end{bmatrix} := u(t)v'(t) - v(t)u'(t)$$

Proposition: Wronskian

Prop: Suppose $p, q, u, v: I \rightarrow \mathbb{R}$ are functions defined on an interval $I \subseteq \mathbb{R}$, such that u and v are solutions to: $y'' + p(t)y' + q(t)y = 0$.

→ Let W be the Wronskian $W(t)$ of u and v . Then exactly one of the following is true:

i) (Case 1) $W(t) = 0$ for all $t \in I$, or

ii) (Case 2) $W(t) \neq 0$ for all $t \in I$

Second-Order Linear Equations (cont.)

5/1/23

Lecture 13

Second-Order Linear Equations (cont.)

(*) Proposition: Wronskian

Prop: Suppose $p, q, u, v: I \rightarrow \mathbb{R}$ are functions defined on interval $I \subseteq \mathbb{R}$ s.t. u, v are solns. to the equation $y'' + p(t)y' + q(t)y = 0$. Let $W(t)$ be the Wronskian of u and v ;
then: i) (Case 1) if $\exists t_0 \in I$ s.t. $W(t_0) = 0$, u and v are linearly dependent;
ii) (Case 2) if $\exists t_0 \in I$ s.t. $W(t_0) \neq 0$, u and v are linearly independent

Theorem: Solutions

THM: Suppose y_1, y_2 are the solutions to the homogeneous equation $y'' + p(t)y' + q(t)y = 0$.
Then the general solution is:

$$y(t; C_1, C_2) = C_1 y_1(t) + C_2 y_2(t), \quad C_1, C_2 \in \mathbb{R} \text{ [General soln.]}$$

Fundamental Solutions

Def: A fundamental set of solutions to a homogeneous second-order linear differential equation $y'' + p'(t)y' + q(t)y = 0$ is a pair y_1, y_2 of linearly independent solutions to the equation.

→ (*) Any other solutions will be variations of the general formula including y_1 and y_2 , i.e. will be of the form $C_1 y_1 + C_2 y_2 [= y(t; C_1, C_2)]$.

(*) y_1, y_2 form a basis of the solution space [linear algebra]

Homogeneous 2nd-Order Linear Equations w/ Constant Coefficients

5/1/23
Lecture 13
(cont.)

Homogeneous 2nd-Order Linear Equations w/ Constant Coefficients (§4.2)

Def: A homogeneous 2nd-order linear differential equation is a differential equation that can be expressed in the form $y'' + py' + qy = 0$; $p, q \in \mathbb{R}$ [constants].

Characteristic Polynomials

Def: Given a homogeneous 2nd-order linear equation $y'' + py' + qy = 0$ ($p, q \in \mathbb{R}$), the associated characteristic polynomial is the quadratic polynomial

$$f(\lambda) = \lambda^2 + p\lambda + q \quad [\text{Characteristic polynomial}];$$

a root of the characteristic polynomial is called a characteristic root.

Characteristic Roots

The roots of a characteristic polynomial can be used to find a general solution, depending on the nature of the roots: λ_1, λ_2 :

Case 1: Distinct real roots ($\lambda_1 \neq \lambda_2, \lambda_1, \lambda_2 \in \mathbb{R}$):

$$\rightarrow \text{General solution: } y(t; C_1, C_2) = C_1 e^{\lambda_1 t} + C_2 e^{\lambda_2 t} \quad (\lambda_1, \lambda_2 \in \mathbb{R}; \lambda_1 \neq \lambda_2)$$

Case 2: Repeated real roots ($\lambda_1 = \lambda_2; \lambda_1, \lambda_2 \in \mathbb{R}$):

$$\rightarrow \text{General solution: } y(t; C_1, C_2) = C_1 e^{\lambda_1 t} + C_2 t e^{\lambda_1 t} \quad (\lambda_1, \lambda_2 \in \mathbb{R}; \lambda_1 = \lambda_2)$$

Case 4: Distinct complex roots ($\lambda_1 = a+bi, \lambda_2 = a-bi; \lambda_1, \lambda_2 \in \mathbb{C}$):

$$\rightarrow \text{General solution: } y(t; C_1, C_2) = C_1 e^{\lambda_1 t} + C_2 e^{\lambda_2 t} \quad (\lambda_1 = \overline{\lambda_2}; \lambda_1, \lambda_2 \in \mathbb{C})$$

\hookrightarrow (*) Given complex soln. $z(t)$, its conjugate $\overline{z(t)}$ is also a solution,

Complex Numbers Review

5/3/23
Lecture 14

Complex Numbers Review

Def: A complex number is a number of the form $z = a + bi$, where $a, b \in \mathbb{R}$ and $i = \sqrt{-1}$ is the imaginary unit. We denote the set of all complex numbers by \mathbb{C} .

Given a complex number $z = a + bi$, we define its real part to be $\text{Re}(z) := a$ and its imaginary part to be $\text{Im}(z) := b$.

Given a complex number $z = a + bi$, we define its complex conjugate $\bar{z} = a - bi$.

Complex functions (i.e. functions $z: D \rightarrow \mathbb{C}$) can also be decomposed into real and imaginary parts, i.e. $z(t) = x(t) + iy(t)$.

i) $\bar{z}(t) = x(t) - iy(t)$ [Complex conjugate]

ii) $\frac{d}{dt} z(t) = \frac{d}{dt} x(t) + i \frac{d}{dt} y(t)$ [Derivative]

Euler's formula: $e^{a+bi} = e^a (\cos b + i \sin b)$

(*) Can be used to split solns. $C_1 e^{a+\lambda_1 t} + C_2 e^{a+\lambda_2 t}$ into real solns. $C_1^* \cos(\lambda t) + C_2^* \sin(\lambda t)$, e.g.

(*) Given a polynomial $f(\lambda) = \lambda^2 + p\lambda + q$ with real coefficients p, q and complex root $\lambda_1 = a + bi$, $\lambda_2 = \bar{\lambda}_1 = a - bi$ is also a complex root (complex roots of real polynomials occur in complex conjugate pairs).

(*) Complex Characteristic Roots

Let $z(t)$ be a complex-valued function which is a solution to $y'' + py' + qy = 0$ ($p, q \in \mathbb{R}$). Then: $\bar{z}(t)$ is also a solution.

$[z(t) = x(t) + iy(t) \text{ is soln.} \rightarrow \bar{z}(t) = x(t) - iy(t) \text{ is also a solution}]$

And since the set of all solutions is closed under linear combinations:

- i) $\text{Re}(z(t)) = x(t)$ is a real-valued solution; and
- ii) $\text{Im}(z(t)) = y(t)$ is a real-valued solution

Inhomogeneous Equations

5/8/23
Lecture 15

Inhomogeneous Equations (§4.3)

Recall: An inhomogeneous 2nd-order linear differential equation is an equation of the form:
 $y'' + p(t)y' + q(t)y = g(t)$, where $g(t)$ is not 0 for all t .

Theorem: Solutions to Inhomogeneous Equations

THM: Suppose $y_p(t)$ is a particular solution to the inhomogeneous equation

$$(A) \quad y'' + p(t)y' + q(t)y = g(t),$$

and y_1, y_2 form a fundamental set of solutions to the corresponding homogeneous equation

$$(B) \quad y'' + p(t)y' + q(t)y = 0,$$

then the general solution to the inhomogeneous equation (A) is of the form:

$$y(t) = y(t; C_1, C_2) = C_1 y_1(t) + C_2 y_2(t) + y_p(t)$$

Method of Undetermined Coefficients

Given an inhomogeneous equation $y'' + py' + qy = g(t)$, where:

i) p and q are constant functions ($p, q \in \mathbb{R}$), and

ii) $g(t)$ is a "nice enough" function, and not a solution to the homogeneous equation $y'' + py' + qy = 0$, then:

→ We can find a particular solution to the inhomogeneous equation $y'' + py' + qy = g(t)$ via guessing a trial solution, based on the nature of $g(t)$.

$$(*) \text{ Ex: } y'' + 4y = \cos(3t) \rightarrow g(t) = \cos(3t), \text{ trial soln: } y_p(t) = a \cos(3t) + b \sin(3t)$$

$$\begin{aligned} \rightarrow y_p'' + 4y_p &= -5a \cos(3t) - 5b \sin(3t) \\ &= g(t) = \cos(3t) \end{aligned}$$

$$\rightarrow a = -\frac{1}{5}; b = 0$$

$$\rightarrow \text{Particular solution: } y_p(t) = -\frac{1}{5} \cos(3t) + 0 \sin(3t)$$

Solutions to Inhomogeneous Equations

5/8/23

Lecture 15

(cont.)

Inhomogeneous Equations (cont.)

(*) Trial Solutions

Define constants $A, B, a, b, r, w \in \mathbb{R}$; polynomial $P(t)$, where $p_0(t), p_1(t)$ are polynomials of the same degree as P . Then, based on the form of the forcing function $g(t)$, the trial solutions are as follows:

$g(t)$	Trial Solution $y_p(t)$
i) $= e^{rt}$	$= ae^{rt}$
ii) $= A\cos(wt) + B\sin(wt)$	$= a\cos(wt) + b\sin(wt)$
iii) $= P(t)$	$= p_0(t)$
iv) $= P(t)\cos(wt)$ or $P(t)\sin(wt)$	$= p_0(t)\cos(wt) + p_1(t)\sin(wt)$
v) $= e^{rt}\cos(wt)$ or $e^{rt}\sin(wt)$	$= e^{rt}(a\cos(wt) + b\sin(wt))$
vi) $= e^{rt}P(t)\cos(wt)$ or $e^{rt}P(t)\sin(wt)$	$= e^{rt}(p_0(t)\cos(wt) + p_1(t)\sin(wt))$

→ (*) If $g(t)$ is a solution to $y'' + p(t)y' + q(t)y = f(t)$, then use the trial solution $y_p(t) = tg(t)$; if that fails, try $y_p(t) = t^2g(t)$.

Superposition Principle

Suppose $y_f(t)$ is a particular solution to the equation $y'' + p(t)y' + q(t)y = f(t)$; and $y_g(t)$ is a particular solution to the equation $y'' + p(t)y' + q(t)y = g(t)$.

→ Then, for constants $a, b \in \mathbb{R}$, the combined function $y(t) := ay_f(t) + by_g(t)$ is a solution to the equation

$$y'' + p(t)y' + q(t)y = af(t) + bg(t) \quad [\text{Soln: } y(t) = ay_f(t) + by_g(t)]$$

(*) Ex: $g(t) = 2t + \cos(2t)$ [$P(t) + A\cos(wt)$]

$$\rightarrow y_p(t) = \underbrace{(a_0t + b_0)}_{p_0(t)} + (a_1\cos(2t) + b_1\sin(2t))$$

Variation of Parameters

5/12/23
Lecture 16

Variation of Parameters (§4.4)

(*) Systems of Equations

Suppose $a, b, c, d, e, f \in \mathbb{R}$ are numbers such that:

$$W := \det \begin{bmatrix} a & b \\ c & d \end{bmatrix} = ad - bc \neq 0.$$

→ Then the system $\begin{cases} ax+by=e \\ cx+dy=f \end{cases}$ has unique solution:

$$\boxed{x = \frac{de-bf}{W}, \quad y = \frac{-ce+af}{W}} \quad [\text{Unique solution}]$$

Variation of Parameters

Suppose $y_1(t), y_2(t)$ is a fundamental set of solutions to the homogeneous equation $y'' + p(t)y' + q(t)y = 0$ and define Wronskian $W(t) := y_1 y_2' - y_1' y_2 \neq 0$ for all t . Then the inhomogeneous equation $y'' + p(t)y' + q(t)y = g(t)$ has, as a particular solution, the following:

$$\boxed{y_p(t) = y_1 \int \frac{-y_2(t)g(t)}{W(t)} dt + y_2 \int \frac{y_1(t)g(t)}{W(t)} dt} \quad [\text{Particular solution}]$$

$$(*) \text{ Ex: } y'' + \frac{1}{t}y' - \frac{1}{t^2}y = \frac{\ln(t)}{t}; \quad y_1(t) = t, \quad y_2(t) = \frac{1}{t}$$

$$\rightarrow W(t) = -\frac{2}{t}$$

$$\rightarrow v_1(t) = \int \frac{-y_2(t)g(t)}{W(t)} dt = \int \frac{-(\frac{1}{t})(\frac{\ln(t)}{t})}{-\frac{2}{t}} dt = \frac{(\ln(t))^2}{4}$$

$$v_2(t) = \int \frac{y_1(t)g(t)}{W(t)} dt = \int \frac{t(\frac{\ln(t)}{t})}{-\frac{2}{t}} dt = \frac{t^2(2\ln(t)-1)}{8}$$

$$y_p(t) = y_1 v_1 + y_2 v_2 = \frac{t(\ln(t))^2}{4} - \frac{t(2\ln(t)-1)}{8} \quad [\text{Particular solution}]$$

Review: Linear Algebra

5/15/22

Lecture 17

Linear Algebra Review (85.1)

Def.: A matrix of size $m \times n$ ($m, n \in \mathbb{N} > 0$) is a rectangular array of real numbers with m rows and n columns, composed of entries / components a_{ij} ($i \in \{1, \dots, m\}; j \in \{1, \dots, n\}$).

$$A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix} \quad [m \times n \text{ matrix } A]$$

(*) An entry a_{ij} can also be referred to as the (i, j) -entry of A

$$A = (a_{ij})_{1 \leq i \leq m, 1 \leq j \leq n}; \quad A = (a_{ij}) \quad [\text{Alternate notation}]$$

(*) $\text{Mat}_{m \times n}(\mathbb{R})$ denotes the set of all real-number-
-entry $m \times n$ matrices (alt: $\mathbb{R}^{m \times n}$)

A matrix with only one column (matrix $\in \text{Mat}_{m \times 1}(\mathbb{R})$) is referred to as a column vector. ($\vec{v} \in \mathbb{R}^m$)

For each $m, n \geq 1$, we define zero matrix $O_{m \times n}$ [$O_{m \times n} \in \text{Mat}_{m \times n}(\mathbb{R})$].

Matrix Arithmetic

Sum: Given two matrices $A, B \in \text{Mat}_{m \times n}(\mathbb{R})$, we define the matrix sum $A+B \in \text{Mat}_{m \times n}(\mathbb{R})$ as the $m \times n$ matrix $(a_{ij} + b_{ij})_{1 \leq i \leq m, 1 \leq j \leq n}$.

Scalar Multiplication: Given a matrix $A \in \text{Mat}_{m \times n}(\mathbb{R})$ and a scalar $\lambda \in \mathbb{R}$, we define the scalar multiple of A by λ ($\lambda A \in \text{Mat}_{m \times n}(\mathbb{R})$) as the $m \times n$ matrix $(\lambda a_{ij})_{1 \leq i \leq m, 1 \leq j \leq n}$.

(*) Rules

$$\text{i) } (A+B)+C = A+(B+C)$$

$$\text{v) } \lambda(A+B) = \lambda A + \lambda B$$

$$\text{ii) } O_{m \times n} + A = A$$

$$\text{vi) } (\lambda_1 + \lambda_2)A = \lambda_1 A + \lambda_2 A$$

$$\text{iii) } (-1)A + A = O_{m \times n}$$

$$\text{vii) } (\lambda_1 \lambda_2)A = \lambda_1 (\lambda_2 A)$$

$$\text{iv) } A+B = B+A$$

$$\text{viii) } 1 \cdot A = A; 0 \cdot A = O_{m \times n}$$

Linear Combinations

Def.: A linear combination of column vectors $v_1, \dots, v_m \in \mathbb{R}^n$ ($n \geq 1$) is an expression of the form:

$$\boxed{\lambda_1 v_1 + \lambda_2 v_2 + \dots + \lambda_m v_m} \quad [\lambda_1, \lambda_2, \dots, \lambda_m \in \mathbb{R}] \quad [\text{Linear combination}]$$

Review: Matrix Equations

5/17/23

Lecture 19

Matrix Equations (§5.2)

Def: Given a matrix $A \in \mathbb{R}^{m \times n}$ and vector $\vec{x} \in \mathbb{R}^n$, we define the product of A and \vec{x} to be the column vector $A\vec{x} \in \mathbb{R}^m$, where $(A\vec{x})_{i,1} = \sum_{k=1}^n A_{i,k} x_k$.

(Alt: $A = [\vec{a}_1, \vec{a}_2, \dots, \vec{a}_n] \rightarrow A\vec{x} = \text{linear combination: } x_1\vec{a}_1 + x_2\vec{a}_2 + \dots + x_n\vec{a}_n$)

(*) The product $A\vec{x}$ only defined if # of columns in A = # of rows in \vec{x}

(*) Properties of Matrix Multiplication

Given $A \in \mathbb{R}^{m \times n}$, $\vec{x}, \vec{y} \in \mathbb{R}^n$, $\alpha \in \mathbb{R}$:

$$(1) A(\alpha\vec{x}) = \alpha A\vec{x} \quad (\text{Scalar multiplication})$$

$$(2) A(\vec{x} + \vec{y}) = A\vec{x} + A\vec{y} \quad (\text{Commutativity})$$

Systems of Equations

Systems of equations can be alternatively expressed as matrix equations,

i.e.:

$$a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1$$

$$a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n = b_2 \quad (\text{System of equations})$$

\vdots

$$a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n = b_m$$

\downarrow

$$\begin{array}{c} \text{Coefficient} \\ \text{matrix} \end{array} \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_m \end{bmatrix}$$

(*) Can be solved via augmented matrix, e.g.

\downarrow

$$A\vec{x} = \vec{b} \quad (\text{Matrix equation})$$

(*) Alt. notation:

$$A = [\vec{a}_1, \vec{a}_2, \dots, \vec{a}_n]$$

$$\rightarrow x_1\vec{a}_1 + x_2\vec{a}_2 + \dots + x_n\vec{a}_n = \vec{b}$$

Review: Spans, Spaces, and Dependence

5/17/23
Lecture 19
(cont.)

Definitions (§5.3)

Def: Given a matrix equation $Ax=b$ (§5.2), we say the equation is homogeneous if $b=\vec{0}$; otherwise, if $b \neq \vec{0}$, then the equation is inhomogeneous.

Definition: Null Space

Def.: Let $A \in \mathbb{R}^{m \times n}$. We define the null space of A to be the set of all solutions \vec{x} to the homogeneous equation $A\vec{x}=\vec{0}$ [the set of all vectors \vec{x} s.t. $A\vec{x}=\vec{0}$]. More formally:

$$N(A) = \text{null}(A) := \{x \in \mathbb{R}^n; A\vec{x} = \vec{0}\} \subseteq \mathbb{R}^n \quad [\text{Null space of } A]$$

(*) $\text{null}(A)$ is a subspace of \mathbb{R}^n [i.e. $\text{null}(A)$ is closed under addition, scalar multi.]

Definition: Span

Def.: Given vectors $\vec{x}_1, \vec{x}_2, \dots, \vec{x}_k \in \mathbb{R}^n$, the span of $\vec{x}_1, \dots, \vec{x}_k$ is the set of all linear combinations of $\vec{x}_1, \dots, \vec{x}_k$.

$$\text{span}(\vec{x}_1, \dots, \vec{x}_k) = \{\alpha_1 \vec{x}_1 + \dots + \alpha_k \vec{x}_k; \alpha_1, \dots, \alpha_k \in \mathbb{R}\} \quad [\text{Span}]$$

Definition: Linear Independence

Def.: Given vectors $\vec{x}_1, \vec{x}_2, \dots, \vec{x}_k \in \mathbb{R}^n$, we say $\vec{x}_1, \dots, \vec{x}_k$ are linearly independent if, for constants $c_1, \dots, c_k \in \mathbb{R}$, $c_1 \vec{x}_1 + c_2 \vec{x}_2 + \dots + c_k \vec{x}_k = \vec{0}$ only when $c_1 = c_2 = \dots = c_k = 0$. In other words, if given $A = [\vec{x}_1, \vec{x}_2, \dots, \vec{x}_k]$, the homogeneous equation $A\vec{c} = \vec{0}$ has exactly one solution $\vec{c} = \vec{0}$.

Def.: Otherwise, we say that $\vec{x}_1, \dots, \vec{x}_k$ are linearly dependent, i.e. when $\exists c_1, c_2, \dots, c_k \in \mathbb{R}$ (c_1, \dots, c_k not all zero) s.t. $c_1 \vec{x}_1 + \dots + c_k \vec{x}_k = \vec{0}$. In this case, such a linear combination $c_1 \vec{x}_1 + \dots + c_k \vec{x}_k = \vec{0}$ is called a nontrivial dependence relation.

(*) As opposed to the trivial relation $c_1 = \dots = c_k = 0$.

Review: Bases and Dimension

5/17/23

Lecture 19
(cont.)

Definitions (§5.3, cont.)

Definition: Basis

Def.: Given a subspace V of \mathbb{R}^n , a basis of V is a collection of linearly independent basis vectors $\vec{v}_1, \dots, \vec{v}_k \in \mathbb{R}^n$ that span V (i.e. $V = \text{span}(\vec{v}_1, \dots, \vec{v}_k)$). Additionally, we define the dimension of V to be the number of vectors in a basis of V .

(*) Rank-Nullity Theorem

THM: Given a matrix A with n columns: $\text{rank}(A) + \dim(\text{null}(A)) = n$

Proposition: Solutions

Prop.: Let $A \in \mathbb{R}^{m \times n}$, $b \in \mathbb{R}^m$ [$b \neq \vec{0}$]. Given the inhomogeneous equation $A\vec{x} = b$, with a particular solution $\vec{x}_p \in \mathbb{R}^n$, the set of all solutions to $A\vec{x} = b$ is the set:

$$\{\vec{x}_p + \vec{x}_h; \vec{x}_h \in \text{null}(A)\}, \text{ [set of all solutions]}$$

consisting of the particular solution \vec{x}_p and a homogeneous solution $\vec{x}_h \in \text{null}(A)$.

Definition: Consistency

Def.: Given $A \in \mathbb{R}^{m \times n}$ and $b \in \mathbb{R}^m$, we say the matrix equation $Ax = b$ is inconsistent if \nexists any solutions \vec{x} to the equation $Ax = b$. Otherwise, we say the equation is consistent.

(*) Notes on Consistency

Given a consistent matrix equation $Ax = b$, there is a unique solution to $Ax = b$ iff $\text{null}(A) = \{\vec{0}\}$. Otherwise, if $\text{null}(A) \neq \{\vec{0}\}$, there are infinitely many solutions to the matrix equation $Ax = b$.

(*) Note on Bases

Given a subspace V of \mathbb{R}^n , V may have infinitely many bases; however, all bases of V will be of the same size (i.e. $\dim(V)$ does not depend on choice of basis).

Review: Determinants

5/19/23

Lecture 20

Square Matrices and Determinants (§5.4)

Def.: A matrix A is called square if $A \in \mathbb{R}^{n \times n}$ for some $n \geq 1$ (i.e. # rows = # columns).

(*) The Identity Matrix

Def.: An identity matrix is a square matrix $I \in \mathbb{R}^{n \times n}$, where: $(I)_{ij} = \begin{cases} 1 & \text{if } i=j \\ 0 & \text{if } i \neq j \end{cases}$ ($\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$, e.g.)

(*) Note: $I\vec{v} = \vec{v} \forall \vec{v} \in \mathbb{R}^n$

Definition: Determinant

Def.: Every square matrix $A \in \mathbb{R}^{n \times n}$ is associated with a number $\det(A) \in \mathbb{R}$, known as the determinant of A (i.e. there exists a function $\det: \mathbb{R}^{n \times n} \rightarrow \mathbb{R}$). Notably, the determinant can be used to determine if $\text{null}(A) = \{\vec{0}\}$ (i.e. if \exists a solution $\vec{v} \neq \vec{0}$ to the equation $A\vec{v} = \vec{0}$).

(*) Computing the Determinant

Def.: Given square matrix $A \in \mathbb{R}^{n \times n}$, $i, j \in \{1, \dots, n\}$, we define the ij -cofactor matrix of A to be the matrix $\tilde{A}_{ij} \in \mathbb{R}^{(n-1) \times (n-1)}$, obtained from removing the i th row and j th column of A .

→ We can use so-called cofactor expansion to compute the determinant of A as follows:

$$\boxed{\det(A) = \sum_{i=1}^n (-1)^{i+j} A_{ij} \cdot \det(\tilde{A}_{ij})} \quad \text{for any } 1 \leq j \leq n \quad (*: \text{can also expand by columns, instead})$$

→ the determinant of a 1×1 matrix is just the contained value.

(*) Notes on Determinants:

Given a matrix $A \in \mathbb{R}^{n \times n}$, $\text{null}(A) = \{\vec{0}\}$ iff $\det(A) \neq 0$.

Also: (1) $\det(I_{n \times n}) = 1$

(2) $\det(\alpha A) [\alpha \in \mathbb{R}] = \alpha^n \det(A)$

Review: Eigenvalues and Eigenvectors

5/19/27
Lecture 20
(cont.)

Eigenvalues and Eigenvectors (§5.5)

Def.: Given square matrix $A \in \mathbb{R}^{n \times n}$ and constant $\lambda \in \mathbb{R}$, we say that λ is an eigenvalue for A if \exists nonzero vector $\vec{v} \in \mathbb{R}^n$ such that $A\vec{v} = \lambda\vec{v}$. Such a vector \vec{v} is called an eigenvector of A associated with λ .

(*) Eigenvalue Theorem

Given $A \in \mathbb{R}^{n \times n}$ and $\lambda \in \mathbb{R}$, the following are equivalent:

$$\lambda \text{ is an eigenvalue of } A \Leftrightarrow \det(A - \lambda I) = 0$$

The Characteristic Polynomial

Def.: Given square matrix $A \in \mathbb{R}^{n \times n}$, the characteristic polynomial of A is the polynomial $p(\lambda) := \det(A - \lambda I)$ [alt: $(\lambda I - A)$], and the equation $p(\lambda) = 0$ is the characteristic equation [of A].

→ The eigenvalues of A are the zeroes of its characteristic polynomial: $p(\lambda) = \det(A - \lambda I) = 0$

Definition: Eigenspaces and Eigenbases

Def.: Given $A \in \mathbb{R}^{n \times n}$ with eigenvalue λ , the eigenspace of λ is the set of all eigenvectors associated with λ [$\neq \vec{0}$], i.e.:

$$E_\lambda := \text{null}(A - \lambda I) \quad [\text{Eigenspace of } \lambda]$$

Def.: Given $A \in \mathbb{R}^{n \times n}$, an eigenbasis of A is a basis of \mathbb{R}^n composed of eigenvectors of A , i.e. a set of vectors $\vec{v}_1, \dots, \vec{v}_n$ s.t.:

- (1) $A\vec{v}_i = \lambda_i \vec{v}_i$ for some λ_i for each $i = 1, \dots, n$;
- (2) $\mathbb{R}^n = \text{span}(\vec{v}_1, \dots, \vec{v}_n)$, or: $\vec{v}_1, \dots, \vec{v}_n$ are linearly independent

(*) Forming Eigenbases

Given $A \in \mathbb{R}^{n \times n}$ with distinct eigenvalues $\lambda_1, \dots, \lambda_k$, for some $k \leq n$. If, given bases B_1, \dots, B_k of the eigenspaces $E_{\lambda_1}, \dots, E_{\lambda_k}$, $|B_1| + |B_2| + \dots + |B_k| = n$ [$\#$ of vectors in bases adds up to n], then $B := B_1 \cup B_2 \cup \dots \cup B_k$ is an eigenbasis of A .

(*) If $k = n$, $B_1 \cup \dots \cup B_k$ is always an eigenbasis.

Systems of Differential Equations

5/22/23

Lecture 21

Systems of Differential Equations (Sec. 1)

Def.: A homogeneous linear system of differential equations (with constant coefficients) is a set of differential equations of the form:

$$\begin{aligned} x_1'(t) &= a_{11}x_1(t) + a_{12}x_2(t) + \dots + a_{1n}x_n(t) \\ x_2'(t) &= a_{21}x_1(t) + a_{22}x_2(t) + \dots + a_{2n}x_n(t) \\ &\vdots \\ x_n'(t) &= a_{n1}x_1(t) + a_{n2}x_2(t) + \dots + a_{nn}x_n(t) \end{aligned} \rightarrow \boxed{\begin{aligned} \begin{bmatrix} x_1'(t) \\ x_2'(t) \\ \vdots \\ x_n'(t) \end{bmatrix} &= \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ & \vdots & & \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_n(t) \end{bmatrix} \\ &\rightarrow \mathbf{x}' = \mathbf{A}\mathbf{x} \end{aligned}}$$

→ A homogeneous linear system can thus be rewritten in the form of a matrix equation, with solutions in the form of vector-valued functions $\mathbf{x}: \mathbb{R} \rightarrow \mathbb{R}^n$.

Proposition: Solutions

Prop.: Suppose $\mathbf{A} \in \mathbb{R}^{n \times n}$ and $\bar{\mathbf{x}} = \{\mathbf{x}_1(t), \mathbf{x}_2(t), \dots, \mathbf{x}_k(t)\}$ are solutions to the system $\mathbf{x}' = \mathbf{A}\mathbf{x}$. Then, for every $c_1, \dots, c_k \in \mathbb{R}$:

$c_1\mathbf{x}_1(t) + c_2\mathbf{x}_2(t) + \dots + c_k\mathbf{x}_k(t)$ is also a solution.

Definition: Linear Independence

Def.: Let $\mathbf{x}_1(t), \mathbf{x}_2(t), \dots, \mathbf{x}_k(t): \mathbb{R} \rightarrow \mathbb{R}^n$ be vector-valued functions. We say that $\mathbf{x}_1(t), \mathbf{x}_2(t), \dots, \mathbf{x}_k(t)$ are linearly independent if the linear combination $c_1\mathbf{x}_1(t) + \dots + c_k\mathbf{x}_k(t)$ equals zero ($= \mathbf{0}$) only when $c_1 = c_2 = \dots = c_k = 0$. Otherwise, we say that $\mathbf{x}_1(t), \mathbf{x}_2(t), \dots, \mathbf{x}_k(t)$ are linearly dependent.

(*) Fact: Solutions

Suppose $\mathbf{x}_1(t), \mathbf{x}_2(t), \dots, \mathbf{x}_k(t)$ are solutions to $\mathbf{x}' = \mathbf{A}\mathbf{x}$. If there is some fixed t_0 where $\mathbf{x}_1(t_0), \mathbf{x}_2(t_0), \dots, \mathbf{x}_k(t_0)$ are linearly dependent, then the functions $\mathbf{x}_1(t), \mathbf{x}_2(t), \dots, \mathbf{x}_k(t)$ are linearly dependent; conversely, if there is some fixed t_0 where $\mathbf{x}_1(t_0), \mathbf{x}_2(t_0), \dots, \mathbf{x}_k(t_0)$ are linearly independent, then the functions $\mathbf{x}_1(t), \mathbf{x}_2(t), \dots, \mathbf{x}_k(t)$ are linearly independent.

Homogeneous Linear Systems w/ Constant Coefficients

5/22/23
Lecture 21
(cont.)

Homogeneous Linear Systems with Constant Coefficients (§6.1, cont.)

Theorem: Solutions

THM.: Suppose $A \in \mathbb{R}^{n \times n}$ and $x_1(t), x_2(t), \dots, x_n(t)$ are n linearly independent solutions to the equation $x' = Ax$. Then $x_1(t), \dots, x_n(t)$ form a fundamental set of solutions, i.e. any arbitrary solution $x_0(t)$ can be expressed uniquely in the form:

$$x_0(t) = c_1 x_1(t) + c_2 x_2(t) + \dots + c_n x_n(t) \quad \text{for every } t \text{ } (c_1, \dots, c_n \in \mathbb{R}).$$

Proposition: Finding Solutions

Prop.: Suppose $A \in \mathbb{R}^{n \times n}$, λ is an eigenvalue of A , and \vec{v} is an eigenvector associated with λ . Then:

$$x(t) := e^{\lambda t} \vec{v} \quad [\text{Solution to } x' = Ax]$$

is a solution to the system $x' = Ax$ satisfying initial condition $x(0) = \vec{v}$.

→ We can construct a fundamental set of solutions for a system $x' = Ax$ from the vectors of an eigenbasis B of A , i.e.

$B = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$, where each vector \vec{v}_i is associated with eigenvalue λ_i .

→ Any solution $x_0(t)$ can be expressed in the form:

$$x_0(t) = c_1 e^{\lambda_1 t} \vec{v}_1 + c_2 e^{\lambda_2 t} \vec{v}_2 + \dots + c_n e^{\lambda_n t} \vec{v}_n.$$

Planar Systems

Lecture 22

Planar Systems (§6.2)

In the 2×2 system case, there are three possible classes of solutions for the characteristic polynomial:

Case 1: Distinct real roots

THM.: Suppose $A \in \mathbb{R}^{2 \times 2}$ has two distinct eigenvalues $\lambda_1, \lambda_2 \in \mathbb{R}$ ($\lambda_1 \neq \lambda_2$). Additionally, suppose v_1 is an eigenvector associated with λ_1 , and v_2 an eigenvector associated with λ_2 . Then the general solution to $x' = Ax$ is:

$$x(t; C_1, C_2) = C_1 e^{\lambda_1 t} \vec{v}_1 + C_2 e^{\lambda_2 t} \vec{v}_2 \quad [\text{General solution: distinct real roots}]$$

Case 2: Complex conjugate roots

THM.: Suppose $A \in \mathbb{R}^{2 \times 2}$ has complex conjugate eigenvalues $\lambda, \bar{\lambda} \in \mathbb{C}$, and \vec{w} is an eigenvector associated with λ . Then $\bar{\vec{w}}$ is an eigenvector associated with $\bar{\lambda}$; thus, the general solution has the form

(i) Complex:

$$x(t; C_1, C_2) = C_1 e^{\lambda t} \vec{w} + C_2 e^{\bar{\lambda} t} \bar{\vec{w}} \quad [\text{Complex-valued solution}]$$

(ii) Real:
(per Euler's)

$$x(t; C_1, C_2) = C_1 e^{at} (\cos(bt) \vec{v}_1 - \sin(bt) \vec{v}_2) + C_2 e^{at} (\sin(bt) \vec{v}_1 + \cos(bt) \vec{v}_2), \quad [\text{Real-valued solution}]$$

where $\lambda = a + bi$ and $\vec{w} = \vec{v}_1 + i\vec{v}_2$

Case 3(i): Double real roots (easy)

THM.: Suppose $A \in \mathbb{R}^{2 \times 2}$ has one eigenvalue λ (of multiplicity 2). Additionally, suppose we can find two linearly independent eigenvectors of A associated with λ . Then the general solution to $x' = Ax$ is:

$$x(t; C_1, C_2) = C_1 e^{\lambda t} \begin{bmatrix} 1 \\ 0 \end{bmatrix} + C_2 e^{\lambda t} \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad [\text{General solution: double real roots (easy case)}]$$

Higher-Order Linear Equations

5/26/23

Lecture 2

Planar Systems (§6.2, cont.)

Case 3(ii): Double real roots (hard)

THM: Suppose $A \in \mathbb{R}^{2 \times 2}$ has one eigenvalue λ (of multiplicity 2). Additionally, suppose we can find only one linearly independent eigenvector \vec{v}_1 of A associated with λ . Then the general solution to $\vec{x}' = A\vec{x}$ is:

$$\vec{x}(t; C_1, C_2) = C_1 e^{\lambda t} \vec{v}_1 + C_2 e^{\lambda t} (\vec{v}_2 + t \vec{v}_1), \quad [\text{General solution: double real roots (hard)}]$$

where \vec{v}_2 is any particular solution to the equation $(A - \lambda I) \vec{v}_2 = -\vec{v}_1$.

Higher-Order Linear Equations (§6.3)

Given a homogeneous n^{th} -order linear equation with constant coefficients:

$$y^{(n)} + a_1 y^{(n-1)} + \dots + a_{n-1} y' + a_n y = 0, \quad \text{with } a_1, \dots, a_n \in \mathbb{R},$$

we can reexpress it as an $n \times n$ linear system $\vec{x}' = A\vec{x}$:

$$\begin{bmatrix} x_1'(t) \\ x_2'(t) \\ \vdots \\ x_{n-1}'(t) \\ x_n'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & 1 \\ -a_n & -a_{n-1} & -a_{n-2} & \dots & -a_1 \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_{n-1}(t) \\ x_n(t) \end{bmatrix} \quad \left[\begin{array}{l} \text{where } x_i(t) := y^{(i-1)}(t), \\ x_{(i+n)}(t) = x_i'(t) \end{array} \right]$$

(*) The matrix A , in this case, is called the companion matrix

Theorem: Solutions

THM: Suppose $A \in \mathbb{R}^{n \times n}$ has n distinct eigenvalues λ_i , with \vec{v}_i being an eigenvector of A associated with λ_i . Then the general solution of the equation $\vec{x}' = A\vec{x}$ is:

$$\vec{x}(t; C_1, \dots, C_n) = C_1 e^{\lambda_1 t} \vec{v}_1 + C_2 e^{\lambda_2 t} \vec{v}_2 + \dots + C_n e^{\lambda_n t} \vec{v}_n,$$

where the topmost row $y(t; C_1, \dots, C_n) = x_1(t)$ of \vec{x} is the solution to the original equation.

Higher-Order Linear Equations (cont.)

Lecture 24

Higher-Order Linear Equations (§6.3, cont.)

Theorem: Solutions

THM.: Consider the n^{th} -order homogeneous linear differential equation w/ constant coefficients:

$$y^{(n)} + a_{n-1}y^{(n-1)} + \dots + a_{n-1}y' + a_n y = 0 \quad (a_0, \dots, a_n \in \mathbb{R}),$$

with associated linear system $x' = Ax$.

(1) The following are equivalent:

(a) $y(t)$ is a solution to the original equation

(b) the vector-valued function

$$x(t) = \begin{bmatrix} y(t) \\ y'(t) \\ \vdots \\ y^{(n-1)}(t) \end{bmatrix}, \quad \text{is a solution to } x' = Ax.$$

(2) Suppose $y_1(t), \dots, y_n(t)$ are solutions to the original equation. The following are equivalent:

(a) $y_1(t), \dots, y_n(t)$ are linearly independent

(b) For some t_0 :

$$\det \begin{bmatrix} y_1(t_0) & y_2(t_0) & \dots & y_n(t_0) \\ y_1'(t_0) & y_2'(t_0) & \dots & y_n'(t_0) \\ \vdots & \vdots & \ddots & \vdots \\ y_1^{(n-1)}(t_0) & y_2^{(n-1)}(t_0) & \dots & y_n^{(n-1)}(t_0) \end{bmatrix} \neq 0$$

(c) For every t :

$$\det \begin{bmatrix} y_1(t) & y_2(t) & \dots & y_n(t) \\ y_1'(t) & y_2'(t) & \dots & y_n'(t) \\ \vdots & \vdots & \ddots & \vdots \\ y_1^{(n-1)}(t) & y_2^{(n-1)}(t) & \dots & y_n^{(n-1)}(t) \end{bmatrix} \neq 0$$

(cont.)

Higher-Order Linear Equations (86.3, cont.)

Definition: Wronskian

Def.: Let $y_1, \dots, y_n: I \rightarrow \mathbb{R}$ be real-valued functions on some interval $I \subseteq \mathbb{R}$. We define the Wronskian of y_1, \dots, y_n to be the function:

$$W(t) := \det \begin{bmatrix} y_1(t) & y_2(t) & \dots & y_n(t) \\ y_1'(t) & y_2'(t) & \dots & y_n'(t) \\ \vdots & \vdots & \ddots & \vdots \\ y_1^{(n-1)}(t) & y_2^{(n-1)}(t) & \dots & y_n^{(n-1)}(t) \end{bmatrix} \quad [\text{Wronskian of } y_1, \dots, y_n]$$

Proposition: Solutions to Higher-Order Linear Equations

Prop.: Suppose $y_1(t), \dots, y_n(t)$ are solutions to:

$$y^{(n)}(t) + a_1 y^{(n-1)}(t) + \dots + a_{n-1} y'(t) + a_n y(t) = 0 \quad (a_1, \dots, a_n \in \mathbb{R})$$

Then $y_1(t), \dots, y_n(t)$ are linearly independent iff $W(t) \neq 0$ iff $W(t_0) \neq 0$ for some fixed t_0 . If so, then the general solution is:

$$y(t) = C_1 y_1(t) + C_2 y_2(t) + \dots + C_n y_n(t) \quad (C_1, \dots, C_n \in \mathbb{R})$$
